Mammalia have two sets (Diphyodont). sometimes only one set (Monophyodont). Possibly in Mammalia there may also exist traces of a Pre-milk set and a Post-permanent set. In all cases (except in Teleost fishes) there is a common tooth band extending all round the jaw, and giving off one, two, or many sets of teeth from its outer (labial) surface. In Mammalia the milk set is usually well developed, but in some it is more or less suppressed. Thus the milk teeth may: --Last all life Whales. Last till full growth is reached.... Horse. Be calcified, but not erupted Elephant seal. Be formed, but not calcified Shrew. Not be formed at all.....Sloths. Sometimes permanent teeth are shed in adult age, as in Dugong, Kangaroo, Wart-hog. In many ungulata, carnivora, and insectivora the first tooth behind the canine is small, cut late, lost early, and has no successor, and it is doubtful if it is a milk or a permanent tooth. The permanent molars are thought by some to be milk teeth, by others to be permanent teeth, and again by others to be a fusion from both sets. The milk dentition resembles the permanent dentition. Hence milk molars resemble permanent molars and not pre-molars, and carnassial teeth are found in milk dentitions. But sexual teeth are ill-developed in milk dentitions, and in the following animals there are other differences: --Orycteropus has heterodont, rooted milk teeth and homodont persistent growing permanent teeth.
