neuroscience textbooks: Neuroscience Carlos M. Contreras, 2012-03-16 The Neuronal Doctrine recently reached its 100th year and together with the development of psychopharmacology by the middle of 20th century promoted spectacular developments in the knowledge of the biological bases of behavior. The overwhelming amount of data accumulated, forced the division of neuroscience into several subdisciplines, but this division needs to dissolve in the 21st century and focus on specific processes that involve diverse methodological and theoretical approaches. The chapters contained in this book illustrate that neuroscience converges in the search for sound answers to several questions, including the pathways followed by cells, how individuals communicate with each other, inflammation, learning and memory, the development of drug dependence, and approaches to explaining the processes that underlie two highly incapacitating chronic degenerative illnesses.

neuroscience textbooks: The Ecological Brain Luis H. Favela, 2023-12-22 The Ecological Brain is the first book of its kind, using complexity science to integrate the seemingly disparate fields of ecological psychology and neuroscience. The book develops a unique framework for unifying investigations and explanations of mind that span brain, body, and environment: the NeuroEcological Nexus Theory (NExT). Beginning with an introduction to the history of the fields, the author provides an assessment of why ecological psychology and neuroscience are commonly viewed as irreconcilable methods for investigating and explaining cognition, intelligent behavior, and the systems that realize them. The book then progresses to its central aim: presenting a unified investigative and explanatory framework offering concepts, methods, and theories applicable across neural and ecological scales of investigation. By combining the core principles of ecological psychology, neural population dynamics, and synergetics under a unified complexity science approach, NExT offers a compressive investigative framework to explain and understand neural, bodily, and environmental contributions to perception-action and other forms of intelligent behavior and thought. The book progresses the conversation around the role of brains in ecological psychology, as well as bodies and environments in neuroscience. It is essential reading for all students of ecological psychology, perception, cognitive sciences, and neuroscience, as well as anyone interested in the history and philosophy of the brain/mind sciences and their state-of-the-art methods and theories.

neuroscience textbooks: Stahl's Essential Psychopharmacology Stephen M. Stahl, 2021-09-16 The fully-updated fifth edition covers the essential information required to become a neurobiologically empowered psychopharmacologist.

neuroscience textbooks: Foundations of the Neuron Doctrine Gordon M Shepherd, 2015-10-06 The neuron doctrine, first formulated in 1891, states that the brain is constructed of individual neurons, organized into functioning circuits that mediate behavior. Above all else, this is the main concept that underlies all of modern neuroscience. This 25th Anniversary Edition of The Foundations of the Neuron Doctrine explains how this theory was the product of an explosion of histological studies and vigorous debates near the end of the nineteenth century by an extraordinary group of scientists, most importantly the leading figure of the time, Santiago Ramon y Cajal of Spain, and includes the foremost nervous system investigators of many countries, such as Albrecht Kolliker, Sigmund Freud, Wilhelm His, August Forel, Fritdjof Nansen and Gustav Retzius.

neuroscience textbooks: Neurotransmitter Actions in the Vertebrate Nervous System Michael Rogawski, 2012-12-06 Intercellular communication via bioactive substances occurs in virtually all multicellular systems. Chemical neurotransmission in the vertebrate nervous system represents a form of signaling of this type. The biology of chemical neurotransmission is complex, involving transmitter synthesis, transport, and release by the presynaptic neuron; signal generation in the target tissue; and mechanisms for termination of the response. The focus of this book is on one aspect of this scheme: the diverse electrophysiological effects induced by different neurotransmitters on targets cells. In recent years, astonishing progress has been made in elucidating the specific physiological signals mediated by neurotransmitters in the vertebrate nervous system, yet, in our view, this has not been adequately recognized, perhaps because the new concepts have yet to filter into neuroscience textbooks. Nevertheless, the principles of neurotransmitter action are critical to advances in many areas of neuroscience, including molecular neurobiology, neurochemistry, neuropharmacology, physiological psychology, and clinical neuroscience. It was the need for a sourcebook that prompted us to engage a group of neurophysiologists to prepare the chapters in this volume. However, there was an additional reason for this book: more and more it seemed that the field, if not yet having reached maturity, at least was approaching adolescence, with strengths in some areas and healthy conflicts in others. At this stage of development a textbook can help to define a field, clarify problems to be resolved, and identify areas for future investigation.

neuroscience textbooks: Technologies of the Mind Stanislav Tregub, 2020-08-08 The brain is the source of sensations, emotions, desires, thoughts, memories, movement and behavior control. All these are aspects of the process we call the Mind. Despite a vast amount of data on the nervous system functioning down to the molecular level, no concept has yet uncovered the physical mechanism and the technology of this process. With this aim in sight, the author continues to develop the Teleological Transduction Theory. The book contains hypotheses about the physical nature of the Mind and provides examples of how physics manifests in the nervous system physiology. It also shows how the Mind’s algorithm produces a reality model with constant updating based on incoming data and performs the self-learning functions. The theory encompasses the physical processes that create the enormous capacity, speed and multi-level complexity of our memory. It solves the riddle of how the brain forms and reproduces a vast number of representations almost instantly. Building a model of reality is not an end to itself. The final goal is to act based on this model. The nervous system specializes in controlling the body and organizing purposeful movement. But how does it perform the function? The book contains hypotheses about the technology and physical mechanism that create the observed speed and efficiency of motion control. Taking all these aspects together, the proposed theory aims to cover the explanatory gap about the physical nature of the Mind.
