Understanding the Fundamentals of Optimal Control

An optimal control course begins with an introduction to the fundamental principles governing control systems and optimization. At its core, optimal control theory is concerned with finding a control policy that will minimize or maximize a performance criterion, often expressed as a cost or reward function, subject to dynamic system constraints. This field extends classical control theory by focusing not only on stabilizing a system but also on optimizing its behavior over time. Understanding the basics of system dynamics, state-space representation, and control inputs is crucial for grasping more advanced topics covered in the course.

Definition and Scope of Optimal Control

Optimal control involves determining control functions that optimize a given performance index while satisfying state and control constraints. The scope includes linear and nonlinear systems, continuous and discrete-time models, and deterministic or stochastic frameworks. The course explores how these concepts apply across various engineering disciplines to improve system efficiency and effectiveness.

Historical Development and Theoretical Foundations

Theoretical foundations of optimal control trace back to the calculus of variations and the pioneering work of Lev Pontryagin and Richard Bellman. The Pontryagin Maximum Principle and Bellman's Dynamic Programming are fundamental results that provide necessary and sufficient conditions for optimality. An optimal control course typically reviews these concepts to establish a solid theoretical base for students.

Core Topics Covered in an Optimal Control Course

The curriculum of an optimal control course is structured to cover a broad range of essential topics. These subjects equip students with the analytical and computational tools necessary for solving optimal control problems across different domains.

optimal control course: **Computational Optimal Control** Roland Bulirsch, Dieter Kraft, 2012-12-06 Resources should be used sparingly both from a point of view of economy and ecology. Thus in controlling industrial, economical and social processes, optimization is the tool of choice. In this area of applied numerical analysis, the INTERNATIONAL FEDERATION OF AUTOMATIC CONTROL (IFAC) acts as a link between research groups in universities, national research

laboratories and industry. For this purpose, the technical committee Mathematics of Control of IFAC organizes biennial conferences with the objective of bringing together experts to exchange ideas, experiences and future developments in control applications of optimization. There should be a genuine feedback loop between mathematicians, computer scientists, engineers and software developers. This loop should include the design, application and implementation of algorithms. The contributions of industrial practitioners are especially important. These proceedings contain selected papers from a workshop on CONTROL APPLICATIONS OF OPTIMIZATION, which took place at the Fachhochschule München in September 1992. The workshop was the ninth in a series of very successful biennial meetings, starting with the Joint Automatic Control Conference in Denver in 1978 and followed by conferences in London, Oberpfaffenhofen, San Francisco, Capri, Tbilisi and Paris. The workshop was attended by ninety researchers from four continents. This volume represents the state of the art in the field, with emphasis on progress made since the publication of the proceedings of the Capri meeting, edited by G. Di Pillo under the title 'Control Applications of Optimization and Nonlinear Programming'.

optimal control course: Optimal Control Leonid T. Aschepkov, Dmitriy V. Dolgy, Taekyun Kim, Ravi P. Agarwal, 2017-01-11 This book is based on lectures from a one-year course at the Far Eastern Federal University (Vladivostok, Russia) as well as on workshops on optimal control offered to students at various mathematical departments at the university level. The main themes of the theory of linear and nonlinear systems are considered, including the basic problem of establishing the necessary and sufficient conditions of optimal processes. In the first part of the course, the theory of linear control systems is constructed on the basis of the separation theorem and the concept of a reachability set. The authors prove the closure of a reachability set in the class of piecewise continuous controls, and the problems of controllability, observability, identification, performance and terminal control are also considered. The second part of the course is devoted to nonlinear control systems. Using the method of variations and the Lagrange multipliers rule of nonlinear problems, the authors prove the Pontryagin maximum principle for problems with mobile ends of trajectories. Further exercises and a large number of additional tasks are provided for use as practical training in order for the reader to consolidate the theoretical material.
